Indicative High Carbon Stock (2020) dataset provides 10 m resolution maps of canopy height and carbon density for Indonesia, Malaysia, and the Philippines. Using the High Carbon Stock Approach (HCSA), vegetation was stratified by estimated aboveground biomass. A deep convolutional neural network was trained on Sentinel-2 imagery with reference data from GEDI LiDAR, and calibrated with airborne LiDAR from Sabah, Borneo. The maps represent conditions between September 2020 and March 2021 and are valuable for forest monitoring, carbon stock assessment, and conservation planning.
